DEDICATION

For Rev. James P. Maier, 1899-1980,
and
Luke David Maier, 1982 and onward.
I wish they could have met.

PREFACE

This book is a revision and extension of notes I wrote for a graduate seminar in relational database theory given at Stony Brook. The purpose of that course was to give students enough background in relational database theory to enable them to understand the current research being done in the field. I have not attempted to be exhaustive in covering all results in relational database theory—the field has already grown too large to cover everything. Instead, I have attempted to get within “one paper” of all current work: This book should give a student sufficient background to read recent papers in relational theory.

While most of the material presented here has been presented before, there is some new material, particularly on annular covers and in the chapter on database semantics. I have tried to bring material together that was available previously only in separate papers, and give some coherence to the results. That task has involved translating many of the results into standard notation, redoing some of the definitions, and constructing some new proofs for previously known theorems.

The book is aimed at a second course in databases, presumably at the graduate level, but possibly at the advanced undergraduate level. While an introductory course in database management systems is not an absolute prerequisite for this book, it is certainly desirable for some concrete motivation and intuition for the abstractions presented here. No specific course in mathematics is assumed, but there should be an acquaintance with set theory and the rudiments of formal logic. Some of the exercises require some sophisticated combinatorics, but those exercises are not central to the topic being developed—they are included for fun. Exercises that are deemed particularly difficult are marked with an asterisk.

Of course, I hope the book also will be a useful reference for researchers already working in the area. The bibliography is current through October 1981; some of the technical reports presumably have since appeared in journals and conference proceedings. I am grateful to Jeff Ullman for an advance copy of the bibliography to the second edition of *Principles of Database Systems*.

ACKNOWLEDGEMENTS

My interest in relational database theory came about in my final spring and summer as a graduate student at Princeton. I have since received much encouragement and many good ideas from the crowd I met there: Catriel Beeri, Peter Honeyman, Hank Korth, Alberto Mendelzon, Fereidoon Sadri, Yehoshua Sagiv, Ed Sciore, Mihalis Yannakakis, Jeff Ullman and, indirectly, Al Aho. My class at Stony Brook suffered bravely through the draft of the first eight chapters. Al Croker was the champion typo finder. Billie Goldstein kept at it for most of the rest of the manuscript. Ron Fagin also offered many suggestions, particularly on multivalued and join dependencies. Two classes have used the notes and relayed comments back to me—one at Penn State taught by Karen Chase, the other at Michigan taught by Joyce Friedman and Steve Tolken. Joyce also served as technical reader for the manuscript. I have also received much advice and amusement from the data semantics cadre here at Stony Brook: David Rozenshtein, Sharon Salveter, Jacob Stein and David Warren. Kaye VanValkenburg, my wife, has been encouraging and forbearing throughout. Finally, I feel immeasurable gratitude for Betty Knittweis, who typed and retyped the majority of the manuscript.
